Certificate of Training

This is to certify that Shri Sridhar Katta a student of Jauaharlal Nehru Technological University, Kakinada has undergone Summer Training at Oil and Natural Gas Corporation Limited, Mehsana Asset from 24th May, 2018 to 28th June, 2018.

He has successfully completed his Project Work on Drilling Services Operation at Oil and Natural Gas Corporation Limited in the discipline of Petroleum Engineering. During the training, he took keen interest in the assigned work. We wish him all success in his future academic endeavours and life.

Date : 28th June, 2018

Place : Mehsana

ACKNOWLEDGEMENTS

I would like to express my profound sense of gratitude to my guide and supervisor, Mr.Naveen Chandra Oli, **DGM(D) HSE, Drilling Services, ONGC MEHSANA ASSET,MEHSANA** for his skillful guidance, timely suggestions and encouragement in completing this project.

I acknowledge my sincere thanks and deep felt gratitude to **Prof. K.V.Rao**, Programme Director, Petroleum Courses, Jawaharlal Nehru Technological University Kakinada for arranging the summer internship program.

I take this opportunity to express my sincere thanks to **Dr. K. Meera Saheb**, Head of the Department, Department of Petroleum Engineering and Petrochemical Engineering for encouraging and motivating me to complete the internship and report successfully.

Also I express my special thanks to our beloved Principal, **Dr. P. Subba Rao** his enthusiastic support in our endeavours.

Finally, I am very much grateful to my parents for their financial support and encouragement throughout the internship programme.

KATTA SRIDHAR

ABSTRACT

This Summer Internship Report describes the one month experiences with the **ONGC MEHSANA Asset**, at Mehsana, during the period of 24th may 2018 to 20th june 2018. It is intended to establish that this experience meets the objectives of the Bachelor of Technology in Petroleum Engineering.

Working as an engineer, I have been involved in a variety of activities relating to engineering Aspects. These undertakings have been described in this report. Major activities have included a Overview of ONGC in India ,Overview of Mehsana Asset,Overview of drilling activites,Cementing activites, Drilling Tool Yard Services (DTYS),Crisis Management Team (CMT) Section,Instrumentation Section, Directional Drilling and Fishing Section and Rig Visits to different drilling rigs in Mehsana asset.

I have been benefited greatly from the internship experience and Last but not least, I would like to thank Mr.Navven Chandra Oli for guiding and supervising me during this internship.

Chapter 1

ABOUT ONGC

Oil and Natural Gas Corporation Limited (ONGC) is an Indian multinational oil and gas company earlier headquartered in Dehradun, Uttarakhand, India. As a Corporation, its registered office is now at Deendayal Uurja Bhavan, Vasant Kunj, New Delhi (110070) India. It is a Public Sector Undertaking (PSU) of the Government of India, under the administrative control of the Ministry of Petroleum and Natural Gas. It is India's largest oil and gas exploration and production company. It produces around 70% of India's crude oil (equivalent to around 30% of the country's total demand) and around 62% of its natural gas.

History of ONGC

1. Foundation to 1961
 - (a) Before the independence of India in 1947, the Assam Oil Company in the north-eastern and Attock Oil Company in north-western part of the undivided India were the only oil producing companies, with minimal exploration input. The major part of Indian sedimentary basins was deemed to be unfit for development of oil and gas resources.
 - (b) After independence, the Central Government of India realized the importance of oil and gas for rapid industrial development and its strategic role in defense. Consequently, while framing the Industrial Policy Statement of 1948, the development of petroleum industry in the country was considered to be of utmost necessity.
 - (c) In 1955, Government of India decided to develop the oil and natural gas resources in the various regions of the country as part of the Public Sector development. With this objective, an Oil and Natural Gas Directorate was set up towards the end of 1955, as a subordinate office under the then Ministry of Natural Resources and Scientific Research. The department was constituted with a nucleus of geoscientists from the Geological Survey of India.
 - (d) Soon, after the formation of the Oil and Natural Gas Directorate, it became apparent that it would not be possible for the Directorate with its limited

financial and administrative powers as subordinate office of the Government, to function efficiently. So in August, 1956, the Directorate was raised to the status of a commission with enhanced powers, although it continued to be under the government. In October 1959, the Commission was converted into a statutory body by an act of the Indian Parliament, which enhanced powers of the commission further. The main functions of the Oil and Natural Gas Commission subject to the provisions of the Act, were "to plan, promote, organize and implement programs for development of Petroleum Resources and the production and sale of petroleum and petroleum products produced by it, and to perform such other functions as the Central Government may, from time to time, assign to it ". The act further outlined the activities and steps to be taken by ONGC in fulfilling its mandate.

2. From 1961 to present

- (a) Since its inception, ONGC has been instrumental in transforming the country's limited upstream sector into a large viable playing field, with its activities spread throughout India and significantly in overseas territories. In the inland areas, ONGC not only found new resources in Assam but also established new oil province in Cambay basin (Gujarat), while adding new petroliferous areas in the Assam-Arakan Fold Belt and East coast basins (both onshore and offshore).
- (b) ONGC became a publicly held company in February 1994, with 20% of its equity were sold to the public and eighty percent retained by the Indian government. At the time, ONGC employed 48,000 people and had reserves and surpluses worth ₹104.34 billion, in addition to its intangible assets. The corporation's net worth of ₹107.77 billion was the largest of any Indian company
- .
- (c) In 2003, ONGC Videsh Limited (OVL), the division of ONGC concerned with its foreign assets, acquired Talisman Energy's 25% stake in the Greater Nile Oil project.
- (d) In 2006, a commemorative coin set was issued to mark the 50th anniversary of the founding of ONGC, making it only the second Indian company (State Bank of India being the first) to have such a coin issued in its honor.
- (e) In 2011, ONGC applied to purchase 2000 acres of land at Dahanu to process offshore gas. ONGC Videsh, along with Statoil ASA (Norway) and Repsol SA (Spain), has been engaged in deep-water drilling off the northern coast of Cuba in 2012. On 11 August 2012, ONGC announced that it had made a large oil discovery in the D1 oilfield off the west coast of India, which will help it to raise the output of the field from around 12,500 barrels per day (bpd) to a peak output of 60,000 bpd.

Table 1.1: Product-wise revenue breakup for FY 2016–17 (₹ billion)

Product	Revenue
Crude Oil	526.38
Gas	168.88
LPG	31.48
Naphtha	36.80
C2-C3	13.44
Others	1.59
Adjustments	-32.74
Total	825.52
Rs.825.52 billion	

- (f) In November 2012, OVL agreed to acquire ConocoPhillips' 8.4% stake in the Kashagan oilfield in Kazakhstan for around US\$5 billion, in ONGC's largest acquisition to date. The acquisition is subject to the approval of the governments of Kazakhstan and India and also to other partners in the Caspian Sea field waiving their pre-emption rights.
- (g) In January 2014, OVL and Oil India completed the acquisition of Videocon Group's ten percent stake in a Mozambican gas field for a total of \$2.47 billion.
- (h) In June 2015, Oil and Natural Gas Corporation (ONGC) gave a Rs27bn (\$427m) offshore contract for the Bassein development project to Larsen & Toubro (L&T).
- (i) In February 2016, the board of ONGC approved an investment of Rs. 5,050 crores in Tripura for drilling of wells and creation of surface facilities to produce 5.1 million standard cubic feet per day gas from the state's fields.
- (j) On 19 July 2017, the Government of India approved the acquisition of Hindustan Petroleum Corporation by ONGC.

Table 1.1 shows the Product-wise revenue breakup for FY 2016–17 (₹ billion) which is shown above.

ONGC Videsh is a wholly owned subsidiary of Oil and Natural Gas Corporation Limited (ONGC), the National Oil Company of India, and is India's largest international oil and gas Company. ONGC Videsh has participation in 41 projects in 20 countries namely Azerbaijan, Bangladesh, Brazil, Colombia, Iraq, Israel, Iran, Kazakhstan, Libya, Mozambique, Myanmar, Namibia, Russia, South Sudan, Sudan, Syria, United Arab Emirates, Venezuela, Vietnam and New Zealand. ONGC Videsh maintains a balanced portfolio of 15 producing, 4 discovered/under development, 18 exploratory and 4 pipeline projects. The Company currently operates/ jointly operates 21 projects. ONGC Videsh had total oil and gas reserves (2P) of about 711 MMTOE as on April 1, 2018.

Chapter 2

ABOUT MEHSANA ASSET

The Mehsana Tectonic Block is a fairly well explored, productive hydrocarbon block of North Cambay Basin. Exploration activity for hydrocarbons by ONGC in the Mehsana Asset commenced in the 1960s and discovered fields are in an advanced stage of exploitation. The Asset has been endowed with a number of oil fields with multilayered pays belonging to Paleocene to middle Miocene age. More than 26 small to medium size oil and gas fields have been established in the Mehsana area of Mehsana-Ahmedabad Tectonic Block. Operational areas for the Mehsana Asset include a Mining Lease(ML) area of 942 Km². In this Asset, 2324 wells have been already drilled. Further, 35 production installations have already been established to complete the hydrocarbon production, storage and delivery cycle. The Asset currently produces 6100 TPD of crude oil and 5 Lakh m³ of natural gas on a daily basis.

Major oil fields within the Asset have been clubbed under six different areas:

1. Becharaji & Lanwa (Area-I)
2. Sathal & Balol (Area-II)
3. Jotana (Area-III)
4. Sobhasan Complex (Area- IV)
5. Nandasan, Linch, Langhnaj, Mansa & other satellite structures (Area-V), and
6. North Kadi (Area-VI)

Area I & II constitute the heavy oil fields of the Mehsana Asset. The Asset, spread over four districts in North Gujarat, covers: Two talukas of Patan and Ahmedabad Districts Six talukas in Mehsana District, and One taluka in Gandhinagar District

The Drilling Process

Drilling operations shall be conducted round-the-clock for 24 hrs. The time taken to drill a well depends on the depth of the hydrocarbon bearing formation and the geological

conditions. ONGC intends to drill wells to a depth range from 1200 to 2000 m. This would typically take 30 - 35 days for each well – however drilling period may increase depending on well depth. In general, a 17 1/2" hole is drilled from the surface up to a predetermined depth and 13 3/8" surface casing is done to cover fresh water sands, prevent caving, to cover weak zones & to provide means for attaching well head & the blowout preventer(BOP). This is followed by drilling of 12 1/4" hole and lowering of 9 5/8" intermediate casing depending upon the depth of the well and anticipated problems in drilling the well. The 8 1/2" holes is drilled up to the target depth of the well cased with 5 1/2" or 7" production casing to isolate the producing zone from the other formations.

In the process of drilling, drilling fluid is used to lift the cutting from the hole to the surface. Drilling fluid is formulated by earth clay and barites. Various types of bio-degradable polymers are also added to maintain the specific parameters of the mud. After completion of production casing the well is tested to determine & analyze various parameters of producing fluid. Table 2.1 shows the Power Requirement of Various Rigs of ONGC described above.

Water based mud, that is ecologically sensitive, will be used and all drilling activities will be conducted as per the requirements of the Oilfield and Mineral Development Rules, 1984 as amended till date. Guidelines issued by the Oil Mines Regulation (OMR) will be followed throughout the drilling process.

The power required for driving the drilling rig, circulation system and for providing lighting shall be generated by DG sets attached with the rig deployed by ONGC from various rigs available with ONGC mentioned in the table.. Fuel used in DG sets shall conform to Bharat Stage IV norms including a sulphur content of <50 mg/kg.

Water Requirement

The drilling operation and maintenance of the drill site facilities have various water requirements. The most significant of these requirements in terms of quantity is that for mud preparation. The other requirements would be for engine cooling, floor / equipment / string washing, sanitation, fire-fighting storage / make-up and drinking. Water for emergency fire fighting would be stored in a pit of 200 m³ capacity and make-up of the same will have to be made on a regular basis. The requirement of water expected for sanitation and drinking purposes of the workers shall be insignificantly low in terms of quantity. ONGC has planned to meet the requirement of water at the drilling site through water supplied by tankers and sourced from nearest ONGC installation. Since, there is no quality criterion for usage of raw water for the various uses mentioned above (other than drinking), the tanker water shall be directly used without any treatment. The potable water requirement shall be met by procuring adequately treated water from off-site locations.

Table 2.1: Power Requirement of Various Rigs of ONGC

Serial no	Rig	packager	KVA
1.	IPS-700-V (Mechanical rig)	Sudhir DG	500
		Caterpillar	438
2.	IPS-700-VI (Mechanical rig)	Jackson	500
		Kirloskar	380

		BHEL	1430
7.	CH Rig,John-10 (Mechanical rig)	Caterpillar	500
		Caterpillar	500
8.	CH Rig,John-19 (Mechanical rig)	Caterpillar	500
		caterpillar	500
9..	CH Rig,John-23 (Mechanical rig)	Caterpillar	500
		Caterpillar	500

Waste Water Generation

The drilling operation would generate waste water in the form of wash water due to washing of equipment, string etc. This waste water along with spill over mud will be diverted to waste water mud pit whose bottom would be lined with HDPE sheet so as to avoid percolation of water contaminants in the soil. Approximately 25 m³ per day of waste water will be discharged in HDPE lined evaporation pit. The domestic sewage generated from the drill site operations will be treated in a septic tank–soak pit system. The septic tank is adequately sized to cater to a volumetric capacity of 4–5 m³ per day.

Air Emissions

The emissions to the atmosphere from the drilling operations shall be from the diesel engines and flaring of associated gas during testing operation in case of hydrocarbon is discovered. In accordance with the Oil Mines Regulations Rules, a flare stack of 9m height will be provided.

Solid and Hazardous Waste Management

The drilling rig system to be employed for drilling will be equipped for the separation of drill cuttings and solid materials from the drilling fluid. The drill cuttings, cut by the drill bit, will be removed from the fluid by the shale shakers (vibrating screens) and centrifuges and transferred to the cuttings containment area.

Chapter 3

DRILLING

Once the geoscientists analyze a prospective oil field and the land is leased, a well is drilled to obtain more information about the reservoir. Not all wells are straight and vertical. Horizontal drilling has become a very profitable way to increase production by having the wellbore contacting more of the formation.

Drilling Rig

A drilling rig is a device used to drill, case and cement oil and gas wells. In drilling an oil well different types of rigs are used. The type used will depend on whether the drilling is being done in sea or on land and also on depth.

Rig Components

The most important rig components include: rig engines, derrick and substructure, hoisting equipment, rotary equipment, mud pumps and BOPs.

Rig Engines:

Rigs suitable for shallow drilling use two engines and deep drilling is achieved by three to four engines.

Derrick and Substructure:

A derrick is a four sided structure of sufficient height and strength. The substructure provides support for the derrick, draw-works and drill string.

Hoisting Equipment

The main function of hoisting equipment is to get the drill string and other necessary equipment in and out of the hole safely and efficiently. The main components of hoisting system include draw-works, crown and travelling block, hooks, drilling line.

Drawworks:

This is an assembly of a rotating drum, a series of shafts, clutches, chains and gears for changing speed and for reversing. It also contains the main brake for stopping the drilling line. The drilling line is wound a number of times around the drum, the end of the line then passes on the crown and travelling block.

Crown block:

A block located at the top of the derrick and is stationary. The crown block provides a means of taking the drilling line from the hoisting drum to the travelling block.

Travelling block:

It is a diamond shaped block. The drilling line is wound continuously on the crown and travelling blocks, with the two outside ends being wound on the hoisting drum.

Hook:

It connects the Kelly or topdrive with the travelling block. The hook carries the entire drilling load.

Rotary Equipment

The main components of Rotary equipment are: Rotary table, Kelly, Swivel.

Rotary table:

The main function of the rotary table is to transfer the rotary motion through a master bushing to the Kelly, to drill pipe, and eventually to the drill bit.

Kelly:

The Kelly is the rotating link between the rotary table and the drill string. Its main functions are transmits rotation and weight-on-bit to the drillbit, supports the weight of the drill string and conveys the drilling fluid from the swivel into the drill string. The Kelly has a hexagonal or square shape cross section. The Kelly is usually provided with two safety valves, one at the top and one at the bottom, called upper and lower Kelly cocks, respectively. The Kelly cock is used to close the inside of the drill string in the event of a kick.

Swivel:

The swivel is installed above the Kelly and its main function is to prevent the rotary motion of the Kelly from being transferred to the drilling line.

Master bushing:

It serves two purposes:

- a) Provides engagement of the Kelly drive bushing with the rotary table.
- b) Provides tapered seating for the slips which hold drill pipe in the rotary table.

Kelly drive bushing:

It engages with the master bushing.

Drill String Components

The main component of the drill string includes drill pipe, drill collars and accessories like stabilizers and reamers.

Drill pipe:

The main function of the drill pipe is to transmit rotary motion and drilling mud under high pressure to the drill bit.

Drill collars:

Drill collars are the predominant component of the bottom hole assembly (BHA). It is used to provide weight on bit.

Stabilizers:

Stabilizers are tools placed above the drill bit and along the bottom hole assembly (BHA) to control hole deviation, dogleg severity and prevent differential sticking. They achieve these functions by centralizing and providing extra stiffness to the BHA.

Reamers:

Reamers are usually run immediately behind the bit to provide a gauge hole.

Drilling Bits

Drill bit crushes the rock under combined action of weight on bit and rotary speed.

Roller Cone Bits: These are made up of three equal-sized cones. Each cone is mounted on bearings which run on a pin that forms an integral part of the bit leg. Nozzles are used to provide constriction in order to obtain high jetting velocities necessary for efficient bit and hole cleaning. Mud pumped through the drill string passes through the bit pin bore and through the three nozzles, with each nozzle accommodating one third of the total flow, if all the nozzles were of the same size. Figure 3.1 shows the image of Roller Cone Bits.

Figure 3.1: A Picture of Roller Cone Bits

Polycrystalline Diamond Compact Bit: PDC bit employs no moving parts. A PDC bit employs a large number of cutting elements, each called a PDC cutter. The PDC cutter is made by bonding a layer of polycrystalline man-made diamond to a cemented tungsten carbide substrate in a high pressure, high temperature process. The diamond layer is composed of many tiny diamonds which are grown together at random orientation for maximum strength and wear resistance. Figure 3.2 shows the image of PDC Bits.

Figure 3.2: A Picture of PDC Bits

Diamond Bit: Diamond is the hardest mineral and also possesses the highest thermal conductivity of any other mineral allowing it to dissipate heat very quickly. These bits are used for drilling hard and abrasive formations. Diamond bits are manufactured as either drilling or coring bits.

Drilling Mud

Drilling Mud or drilling fluid is a critical component in the rotary drilling processes.

The primary functions of drilling fluids are:

- Remove cuttings from the wellbore.
- Prevent formation fluids from entering into the wellbore.
- Maintain wellbore stability
- Cool and Lubricate the bit
- Transmit Hydraulic Horsepower to bit

Types of Drilling fluids

The two major types of mud system used are Oil Based Mud which consists of oil as a continuous phase and other is Water Based mud which consists of water as a continuous phase. Mostly water based mud is used in Mehsana. The following mud systems are in continuous use in Mehsana Asset:

- (a) SPUD Mud
- (b) KPPA Mud
- (c) NDDF Mud

(a) Spud Mud:

Mud used to drill a well from the surface to a shallow depth. Onshore spud mud consists of bentonite clay whereas in offshore guar gum and salt gel are used in offshore.

(b) KPPA Mud:

It is an abbreviation of KCL, PHPA, polyol mud. KCL and PHPA in the mud acts as a shale inhibitor and polyol provides lubricity to the mud.

(c) NDDF Mud

It is generally used near pay zone. It is an abbreviation of Non Damaging Destructive Fluid which does not use barite but polymers as a weighing agent as barite is non biodegradable and damages the pay zone permeability and porosity.

Field Tests on Drilling Mud

The mud properties are regularly monitored by mud engineer. These measurements will be used to determine if the properties of mud have been deteriorated and require treatment or not.

The following tests are used to determine the under mentioned :

- Mud Density

The density of the drilling mud can be determined with the mud balance shown in Figure. The cup of the balance is completely filled with a sample of the mud and the lid placed firmly on top (some mud should escape through the hole in the lid). The balance arm is placed on the base and the rider adjusted until the arm is level. The density can be read directly off the graduated scale at the left-hand side of the rider. Figure 3.3 shows the image of Mud balance.

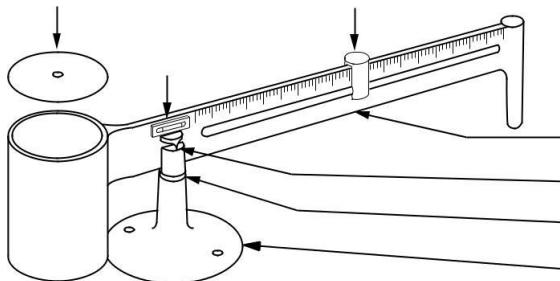

Figure 3.3: A Picture of Mud Balance

- Viscosity

The rheological character of drilling fluids is discussed at length in the chapter on Drilling Hydraulics. In general terms however, viscosity is a measure of a liquids resistance to flow. Two common methods are used on the rig to measure viscosity. Figure 3.4 shows the image of Marsh Funnel Viscometer.

The marsh funnel viscometer is used to make the quickest analysis of the viscosity of drilling fluid. However this device only gives change in viscosity and does not quantify rheological properties such as yield point and plastic viscosity for which we use rotational viscometer.

Rotational viscometer: The multi-rate rotational viscometer is used to quantify the rheological properties of the drilling mud. The assessment is made by shearing a sample of the mud, at a series of prescribed rates and measuring the shear stress on the fluid at these different rates.

- Gel Strength

The gel strength of the drilling mud can be thought of as the strength of any internal structures which are formed in the mud when it is static. The gel strength of the mud will provide an indication of the pressure required to initiate flow after the mud has been static for some time. The gel strength of the mud also provides an indication of the suspension properties of the mud and hence its ability to suspend cuttings when the mud is stationary. It is measured using rotational viscometer by measuring viscosity at 3rpm and after 10 seconds.

- Filtration

The filter cake building properties of mud can be measured by means of a filter press. The following are measured during this test :

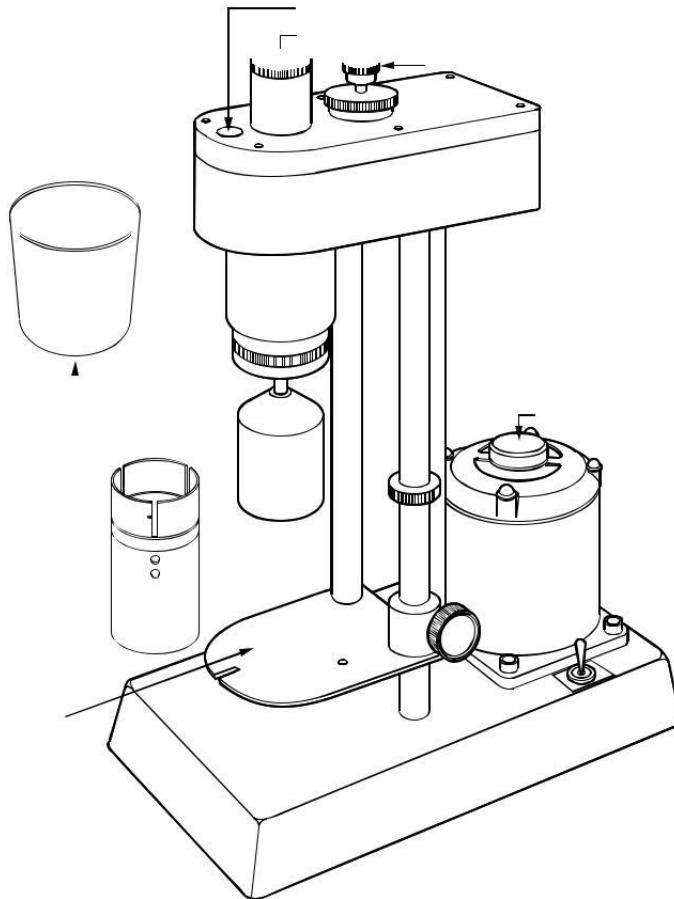

Figure 3.4: A Picture of Marsh Funnel Viscometer

1. The rate at which fluid from a mud sample is forced through a filter under specified temperature and pressure.
2. The thickness of the solid residue deposited on the filter paper caused by the loss of fluids.

- pH Determination

The pH of the mud will influence the reaction of various chemicals and must therefore be closely controlled. The pH test is a measure of the concentration of hydrogen ions in an aqueous solution. This can be done either by pH paper or by a special pH meter.

A pH of 7.0 is neutral, a pH lower than 7.0 is in the acidic range, and a pH higher than 7.0 is in the alkaline range. Drilling fluid additives were developed to be mixed with water with a pH level from 8.5 to 10 in order for the required chemical reaction to occur and to provide a proper yield. Most water sources range from 5.5 to 7.5 which is too low.

The easiest way to check pH level is to use a simple pH testing strip, similar to ones sold to check swimming pool water.

Chapter 4

MUD CONDITIONING EQUIPMENT

Mud Pump: Sucks mud from the mud pits and pumps it to the drilling apparatus.

Shale shaker: Separates rock cuttings from the mud.

Mud pit: In mud pits drilling mud is mixed and recycled.

Reserve pit: It collects rock cuttings separated from the mud.

Mud-mixing hopper: In this new mud is mixed and then sent to the mud pits.

Desander and Desilter: In desander sand particles are removed while in desilter small silt particles are removed.

Figure 4.1 shows the image of Mud Conditioning Equipment.

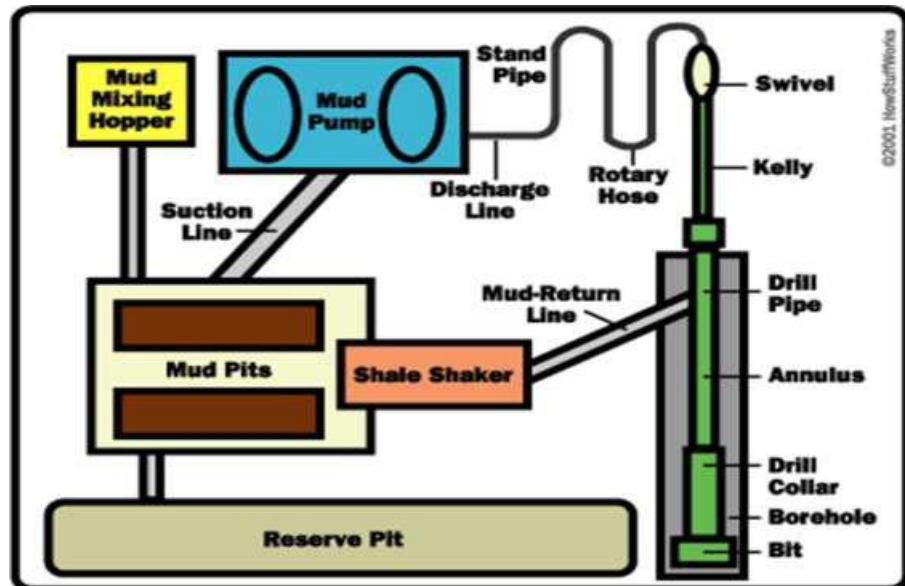

Figure 4.1: A Picture of Mud Conditioning Equipment

Chapter 5

CEMENTING

Cementing operations consist in placing an appropriate cement slurry in the annulus between the walls of the hole and the casing that has been run in. There are several types of cementing jobs and each one meets a particular need.

PURPOSE:

- Isolating a producing formation from adjacent beds.
- Securing the casing mechanically to the borehole walls.
- Protecting casing from corrosion by fluids contained in the beds that have been drilled.
- Providing a leak-proof base for safety and control equipment that is installed on the wellhead.
- Injecting extra cement through the perforations in the casing to consolidate or repair the primary cementing job.
- Sealing off a depleted productive layer.
- Isolating a bed from adjacent zones to reduce the per cent of water or gas in oil production.
- Seal off water influxes.
- Plug up lost circulation zones.
- Serve as the basis of a side track.

Primary Cementation:

It occurs in 4 stages:

1. The first stage comprises of displacing top plug with pre flush which is water. The bottom plug cleans up the well by displacing mud and water occupies its place.

2. Then cement slurry is followed after pre flush is added.
3. Once the pre calculated slurry volume has been added, top plug is displaced again by spacer (water).
4. Pressure is applied in this process and once the top plug rests upon bottom plug the bottom plug breaks and tremendous increase in pressure is noted which tells us the cement job.

Figure 5.1 shows the process of Primary Cementing operations.

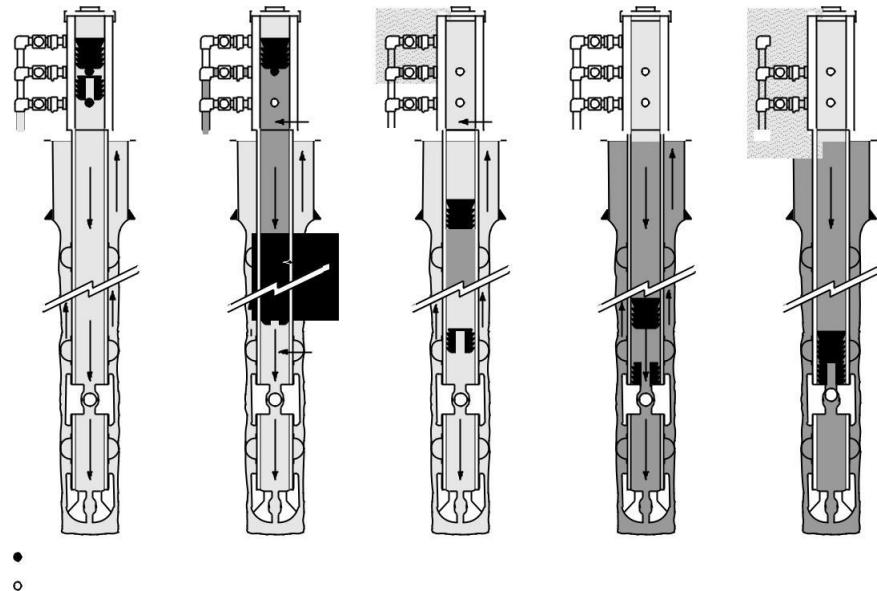

Figure 5.1: A Picture of primary cementing operations

Cementing is performed when the cement slurry is deployed into the well via pumps, displacing the drilling fluids still located within the well, and replacing them with cement. The cement slurry flows to the bottom of the wellbore through the casing, which will eventually be the pipe through which the hydrocarbons flow to the surface. From there it fills in the space between the casing and the actual wellbore, and hardens. This creates a seal so that outside materials cannot enter the well flow, as well as permanently positions the casing in place.

PREPARING THE CEMENT:

In preparing a well for cementing, it is important to establish the amount of cement required for the job. This is done by measuring the diameter of the borehole along its depth, using a caliper log. Utilizing both mechanical and sonic means, multi finger caliper logs measure the diameter of the well at numerous locations simultaneously in order to accommodate for irregularities in the wellbore diameter and determine the volume of the open hole. Additionally, the required physical properties of the cement are essential before commencing cementing operations. The proper set cement is also determined, including the density and viscosity of the material, before actually pumping the cement into the hole.

Special mixers, including hydraulic jet mixers, recirculating mixers or batch mixers, are used to combine dry cement with water to create the wet cement, also known as slurry. The cement used in the well cementing process is Portland cement, and it is calibrated with additives to form one of eight different API classes of cement. Each is employed for various situations. Additives can include accelerators, which shorten the setting time required for the cement, as well as retarders, which do the opposite and make the cement setting time longer. In order to decrease or increase the density of the cement, lightweight and heavyweight additives are added.

Additives can be added to transform the compressive strength of the cement, as well as flow properties and dehydration rates. Extenders can be used to expand the cement in an effort to reduce the cost of cementing, and antifoam additives can be added to prevent foaming within the well. In order to plug lost circulation zones, bridging materials are added, as well.

CEMENTING THE WELL

After casing, or steel pipe, is run into the well, an L-shaped cementing head is fixed to the top of the wellhead to receive the slurry from the pumps. Two wiper plugs, or cementing plugs, that sweep the inside of the casing and prevent mixing: the bottom plug and the top plug. Keeping the drilling fluids from mixing with the cement slurry, the bottom plug is introduced into the well, and cement slurry is pumped into the well behind it. The bottom plug is then caught just above the bottom of the wellbore by the float collar, which functions as a one-way valve allowing the cement slurry to enter the well. Then the pressure on the cement being pumped into the well is increased until a diaphragm is broken within the bottom plug, permitting the slurry to flow through it and up the outside of the casing string.

After the proper volume of cement is pumped into the well, a top plug is pumped into the casing pushing the remaining slurry through the bottom plug. Once the top plug reaches the bottom plug, the pumps are turned off, and the cement is allowed to set. The amount of time it takes cement to harden is called thickening time or pump ability time. For setting wells at deep depths, under high temperature or pressure, as well as in corrosive environments, special cements can be employed.

Additives can be added to transform the compressive strength of the cement, as well as flow properties and dehydration rates. Extenders can be used to expand the cement in an effort to reduce the cost of cementing, and antifoam additives can be added to prevent foaming within the well. In order to plug lost circulation zones, bridging materials are added, as well.

Chapter 6

DRILLING TOOL YARD SERVICES (DTYS)

Drill Bits:

A drilling bit is the cutting or boring tool which is made up on the end of the drill string. The bit drills through the rock by scraping, chipping, gouging or grinding the rock at the bottom of the hole. Drilling fluid is circulated through passageways in the bit to remove the drilled cuttings.

There are basically three types of drilling bits:

- (a) Drag bits
- (b) Roller Cone bits
- (c) Diamond bits

Drag bits:

Drag bits were the first bits used in rotary drilling, but are no longer in common use. A drag bit consists of rigid steel blades shaped like a fish-tail which rotate as a single unit. These simple designs were used up to 1900 to successfully drill through soft formations. The introduction of hard facing to the surface of the blades and the design of fluid passageways greatly improved its performance. Due to the dragging/scraping action of this type of bit, high RPM and low WOB are applied.

Roller Cone Bits:

Roller cone bits (or rock bits) are still the most common type of bit used worldwide. The cutting action is provided by cones which have either steel teeth or tungsten carbide inserts. These cones rotate on the bottom of the hole and drill hole predominantly with a grinding and chipping action. Rock bits are classified as milled tooth bits or insert bits depending on the cutting surface on the cones.

Diamond bits:

A new generation of diamond bits known as polycrystalline diamond compact (PDC) bits were introduced in the 1980's. These bits have the same advantages and disadvantages as natural diamond bits but use small discs of synthetic diamond to provide the scraping cutting surface. The small discs may be manufactured in any size and shape and are not sensitive to failure along cleavage planes as with natural diamond. PDC bits have been run very successfully in many areas around the world. They have been particularly successful (long bit runs and high ROP) when run in combination with turbo drills and oil based mud.

Blowout Preventers:

The blowout prevention (BOP) equipment is the equipment which is used to shut-in a well and circulates out an influx if it occurs. The main components of this equipment are the blowout preventers or BOP's. These are valves which can be used to close off the well at surface. In addition to the BOP's the BOP equipment refers to the auxiliary equipment required to control the flow of the formation fluids and circulate the kick out safely .

There are 2 basic types of blowout preventer used for closing in a well:

- Annular Preventer
- Ram Type

• Annular Preventer:

The main component of the annular BOP is a high tensile strength, circular rubber packing unit. The rubber is molded around a series of metal ribs. The packing unit can be compressed inwards against drill pipe by a piston, operated by hydraulic power. The advantage of such a well control device is that the packing element will close off around any size or shape of pipe. An annular preventer will also allow pipe to be stripped in (run into the well whilst containing annulus pressure) and out and rotated, although its service life is much reduced by these operations. The rubber packing element should be frequently inspected for wear and is easily replaced.Fig 6.1 shows the image of Annular BOP.

• Ram Type Preventers:

Ram type preventers derive their name from the twin ram elements which make up their closing mechanism. Three types of ram preventers are available: Blind rams - which completely close off the wellbore when there is no pipe in the hole.

Figure 6.1: A Picture of Annular BOP

- Pipe rams - which seal off around a specific size of pipe thus sealing of the annulus. In 1980 variable rams were made available by manufacturers. These rams will close and seal on a range of drill pipe sizes.
- Shear rams which are the same as blind rams except that they can cut through drill pipe for emergency shut-in but should only be used as a last resort. A set of pipe rams may be installed below the shear rams to support the severed drill string. Fig 6.2 shows the image of Pipe Ram and shear Ram BOP.

Figure 6.2: A Picture of Pipe Ram and Shear Ram BOP

An accumulator or Koomey unit is a unit used to hydraulically operate Rams BOP, Annular BOP, HCR and some hydraulic equipment. There are several of high pressure cylinders that store gas (in bladders) and hydraulic fluid or water under pressure for hydraulic activated systems. The primary purpose of this unit is to supply hydraulic power to the BOP stack in order to close/open BOP stack for both normal operational and emergency situation.

Chapter 7

CRISES MANAGEMENT TEAM (CMT) SECTION

Crisis management is the process by which an organization which deals with a disruptive and unexpected action that threatens to harm the organization or its stakeholders. The study of crisis management originated with large scale industrial and environmental disaster in 1980's. It is considered to be the most important process in public relations.

Three elements are common to crises:

1. Threat to the organization
2. The element of surprise
3. Short decision time

In contrast to risk management, which involves assessing the potential threat and finding the best ways to avoid the threats, crisis management involves dealing with threats before, during and after they have occurred. It is a discipline within a broader context of management consisting of skills and techniques required to identify, assess understand and cope with a serious situation especially from the moment it first occurred to the point that recovery procedure start.

Crisis management only has to happen because systems fail, so policies and procedures must do all they can to help to prevent incidents from happening in the first place. Effective contingency planning, implemented by a strong, capable and robust team, should minimise their impact if they do.

Staffing specialists must ensure they have an in-depth understanding of the health and safety issues faced by the sector. In this way they can help support their clients and help ensure that if the worst happens, the right people are in place to deal with any consequences.

Chapter 8

INSTRUMENTATION SECTION

It is often said that the proliferation of knowledge and the accelerating development of technology have rendered our environment so complex that no one can understand even a small portion of it. The statement would have been undoubtly correct except for the circumstance that new knowledge can be better organized and that automation can relieve us of a considerable number of chores, as a consequence of which activity can be concentrated on subjects having technological meaning.

In this evolution, clear presentation of modern instruments is of great importance. As machines are being increasingly applied , not only to replace human muscle, but also to develop a good substitute for the routine functions of the of human brains, it becomes more and more important to have an up-to-date summary of technological aids as they become available.

ONGC drills exploratory and development wells all over India as well as a few international locations through a fleet of 75 land rigs and 10 offshore rigs . Well depths vary from a few hundred to a few thousand feet below the surface of the earth. Each rig is equipped with a array of instrumentation monitors which help the driller to drill a hole efficiently and safely. For a driller the drilling rig instrumentation system is like extended hands and eyes of the driller so as to reach where his hands cannot reach and see what his eyes cannot see. Drilling rigs are therefore very critical as it helps to monitor various drilling parameters for smooth, efficient and safe drilling operations. These systems are at present conventional hydro-electrical-mechanical systems. Revamping and up gradation of these systems to state of art systems is in progress under Project PROMISE. All the ONGC owned rigs shall be linked to the enterprise wide SCADA system for proper monitoring, coordination and creating data archives for future analysis of the drilling data.

No engineering services can successfully complete its assignment until it has a full support of its provisioning and technical support group whose main task is to plan, coordinate and ensure that all technical support, by way of requisite spares and systems, are made available right on time so that the maintenance teams can carry out the repair and maintenance of the systems hence adhering to their maintenance schedules.

A team of qualified instrumentation engineers with some amount of field exposure, a flare for drawing up specification and data sheets and vast exposure to the world market so as to update the vendor data base would be essential. Other support groups like the QAD, SHE and Management also need the services of qualified Instrumentation engineers for proper coordination, implementation and compliance of directives of various statutory bodies in their respective fields of activities around ONGC.

Drillometer:

One of the instruments that the driller uses to monitor and improve the operating efficiencies of the drilling operation. The actual measurement of weight is made with a hydraulic gauge attached to the dead line of the drilling line. As tension increases in the drilling line, more hydraulic fluid is forced through the instrument, turning the hands of the indicator.

The weight that is measured includes everything exerting tension on the wire rope, including the traveling blocks and cable itself. Hence, to have an accurate weight measurement of the drill string, the driller must first make a zero offset adjustment to account for the traveling blocks and items other than the drill string. Then the indicated weight will represent the drill string (drill pipe and bottomhole assembly). However, the driller is only nominally interested in this weight for most operations. The weight of interest is the weight applied to the bit on the bottom of the hole. The driller could simply take the rotating and hanging off bottom weight, say 300,000 pounds [136,200 kg], and subtract from that the amount of rotating on bottom weight, say 250,000 pounds [113,50 kg], to get a bit weight of 50,000 pounds [22,700 kg]. Figure 8.1 shows the image of Drillometer.

Figure 8.1: A Picture of Drillometer

Chapter 9

DIRECTIONAL DRILLING AND FISHING SECTION

Reasons for drilling directional wells are:

1. Multi-well Platform Drilling
2. Fault Drilling
3. Inaccessible Locations
4. Salt domes
5. Relief Wells

1. **Multi-well Platform Drilling:** Multi-well Platform drilling is widely employed in the North Sea. The development of these fields is only economically feasible if it is possible to drill a large number of wells (up to 40 or 60) from one location (platform). The deviated wells are designed to intercept a reservoir over a wide areal extent. Many oilfields (both onshore and offshore) would not be economically feasible if not for this technique.
2. **Fault Drilling:** If a well is drilled across a fault the casing can be damaged by fault slippage. The potential for damaging the casing can be minimized by drilling parallel to a fault and then changing the direction of the well to cross the fault into the target.
3. **Inaccessible Locations:** Vertical access to a producing zone is often obstructed by some obstacle at the surface (eg. Estuary, mountain range etc. In this case the well can be directionally drilled to reach the target from a rig site some distance away from the point vertically above the required point of entry of the reservoir.
4. **Salt domes:** Salt domes (called Diapirs) often form hydrocarbon traps in what were overlying reservoir rocks. In this form of trap the reservoir is located directly beneath the flank of the salt dome. To avoid potential drilling problems in the salt (e.g. severe washouts, moving salt, high pressure blocks of dolomite) a directional

well can be used to drill alongside the Diapir (not vertically down through it) and then at an angle below the salt to reach the reservoir.

5. **Relief Wells:** If a blow-out occurs and the rig is damaged, or destroyed, it may be possible to kill the “wild” well by drilling another directionally drilled well (relief well) to intercept or pass to within a few feet of the bottom of the “wild” well. The “wild” well is killed by circulating high density fluid down the relief well, into and up the wild well.

Fishing Tools:

- **Junk Sub:** A down hole tool with a proliferated external surface designed to catch and retrieve junk or debris from the wellbore. The debris is carried up the tool string annulus in the circulation fluid. An indented profile creating a larger annular area causes the fluid flow rate to drop and allows the debris to drop into a basket or receptacle located at the base of the tool. Figure 9.1 shows the image of Junk sub.

Figure 9.1: A Picture of Junk sub

- **Reverse Circulation Junk Basket:** The Reverse Circulation Junk basket or RCJB is used to retrieve all types of small junk objects in wellbore. By producing a circulating force with jet nozzles the junk basket is capable of retrieving the most stubborn items in the hole bottom such as bit rollers, bit bearings, tong dies, hand tools. The Assembly consists of top sub, bowl, junk catcher, valve assembly and shoe. The reverse circulation is made possible by hollow barrel. Figure 9.2 shows the image of Reverse Circulation Junk Basket.
- **Overshot:** Overshot is a positive engagement and disengageable tool. Positive engagement means the overshot is capable of withstanding even jarring impact (F.S. type). Disengageable means, it can be disengaged from the fish at any position/depth. It is designed to catch smooth round tubular o/d fish. The standard overshot is as the equivalent tool joint strength for screw in connection, Excluding slim hole overshot.

Figure 9.2: A Picture of Reverse Circulation Junk Basket

Figure 9.3: A Picture of overshot

It can be disengaged from fish on requirement basis. Figure 9.3 shows the image of Overshoot.

- **Fishing Magnet:** It is used to retrieve undrillable material having magnetic attraction. Small odd shaped items like bit rollers, dies, tong pins etc. which cannot be retrieve by any outside or inside catching tools. They can be run on wire line or drill string. Figure 9.4 shows the image of Fishing magnet.

Figure 9.4: A Picture of Fishing Magnet

- **Die Collar:** Rotary Die Collar are the simplest fishing tool available for engaging a fish externally. This is not a positive engagement tool. It consists of wickers which are non-fluted design if circulation is required below the stuck point. Fluted type design also available to flush cutting while engaging fish. Figure 9.5 shows the image of Die collar.

Figure 9.5: A Picture of Die Collar

Drilling problems

It is almost certain that problems will occur while drilling a well, even in very carefully planned wells. For example, in areas in which similar drilling practices are used, hole problems may have been reported where no such problems existed previously because formations are nonhomogeneous. Therefore, two wells near each other may have totally different geological conditions.

Types of drilling problems:

In well planning, the key to achieving objectives successfully is to design drilling programs on the basis of anticipation of potential hole problems rather than on caution and containment. Drilling problems can be very costly. The most prevalent drilling problems include:

- Pipe sticking
- Loss of circulation
- Hole deviation
- Pipe failures
- Borehole instability
- Mud contamination
- Formation damage
- Hole cleaning
- H₂S-bearing zones
- Shallow gas zones

Chapter 10

CASE STUDIES

1. Rig Visit-RIG-IPS-M700

- Location:

Sobahasan Field Cardwell 6

Rig Name-IPS M700-6

Rig Type-Mechanical Mobile

BOP Type-13 5/8 " 5000 psi Double Ram and 5 5/8 " 5000 psi Annular BOP

- Mud Pump

Power-1250 hP

Power (in KW) - 700KWs

- Well Details

Well Name-SBLR

Target Depth-1953.4 m

True Vertical Depth- 1920 m

Spud date- 29 th May'18

Well Profile-Inclined Well (Directional Drilling)

Kick Off Point-750 m

Net Horizontal Drift-138.98m

Angle-14.81 degrees

Azimuth- 24.1 degrees North

Pay Zone- 1441 m

Observations at the Rig site are:

- Cementing Job was being done.Fig 10.1 shows the image of the Rig
- 500m depth was drilled.
- Casing Policy- 2 CP (9 5/8 " Conductor Casing and 5 1/2 " Production Casing).
- Specific Gravity of Cement- 1.83.

- Class of Cement- Class G.
- Thickening Time- 2- 3hours.

Figure 10.1: A Picture of the Rig IPS-M700

2. Rig E-760-18

- Location- Jotana
 - Rig Name- E-760-18
 - Rig Type- Electrical
 - BOP Rating- 13 3/8 " 5000 psi double ram, 13 5/8 " 5000 psi annular preventer
 - Mud Pump:Power-1000hp
- Well Details:
- Well Name- JNHL
 - Well Type- Development
 - Well Profile-Inclined
 - Target Depth-2204 m

Well logging was being done and logging crew was taking the open hole caliper log.

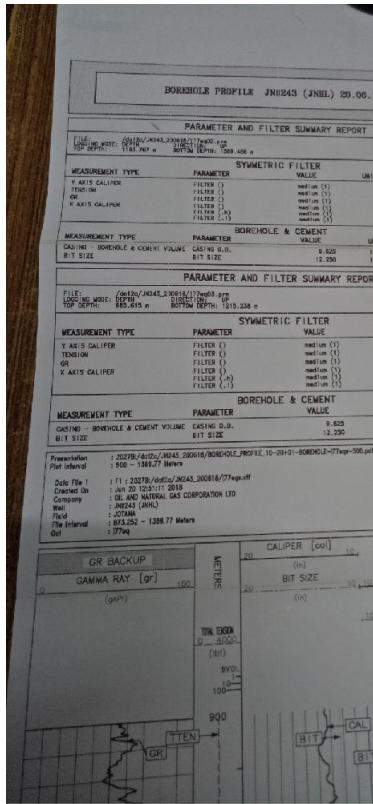

Figure 10.2: A Picture of the Caliper log

Caliper Log: A caliper log is a well logging tool that provides a continuous measurement of the size and the shape of borehole along its depth and is commonly used in hydrocarbon exploration and development wells during drilling to keep a check on the hole size. Fig 10.2 shows the image of the caliper log.

The caliper tool measures the variation in the borehole diameter as it is withdrawn from the bottom of the hole, using two or more articulated arms that push against the bore hole wall. Each arm is typically connected to a potentiometer which causes the resistance to change as the diameter of the hole changes.

A caliper log is a well logging tool that provides a continuous measurement of the size and shape of a borehole along its depth[1] and is commonly used in hydrocarbon exploration when drilling wells. The measurements that are recorded can be an important indicator of cave ins or shale swelling in the borehole, which can affect the results of other well logs. Known challenges with caliper logging include borehole spiralling. The position of the drill bit may precess as it drills, leading to spiraling shapes in the wellbore wall, as if the hole had been drilled by a screw. If the arms of the caliper log follow the grooves of the spiral, it will report too high an average diameter. Moving in and out of the grooves, the caliper will give erratic or periodically varying readings.
